**Abstract**

**AIM:** To evaluate the safety, efficacy and tolerability of *Nigella sativa* (*N. sativa*) in patients with hepatitis C not eligible for interferon (IFN-α).

**METHODS:** Thirty patients with hepatitis C virus (HCV) infection, who were not eligible for IFN/ribavirin therapy, were included in the present study. Inclusion criteria included: patients with HCV with or without cirrhosis, who had a contraindication to IFN-α therapy, or had refused or had a financial constraint to IFN-α therapy. Exclusion criteria included: patients on IFN-α therapy, infection with hepatitis B or hepatitis I virus, hepatocellular carcinoma, other malignancies, major severe illness, or treatment non-compliance. Various parameters, including clinical parameters, complete blood count, liver function, renal function, plasma glucose, total antioxidant capacity (TAC), and polymerase chain reaction, were all assessed at baseline and at the end of the study. Clinical assessment included: hepatomegaly, jaundice, palmar erythema, flapping tremors, spider naevi, lower-limb edema, and ascites. *N. sativa* was administered for three successive months at a dose of (450 mg three times daily). Clinical response and incidence of adverse drug reactions were assessed initially, periodically, and at the end of the study.

**RESULTS:** *N. sativa* administration significantly improved HCV viral load (380808.7 ± 610937 vs 147028.2 ± 475225.6, *P* = 0.001) and TAC (1.35 ± 0.5 vs 1.61 ± 0.56, *P* = 0.001). After *N. sativa* administration, the following laboratory parameters improved: total protein (7.1 ± 0.7 vs 7.5 ± 0.8, *P* = 0.001), albumin (3.5 ± 0.87 vs 3.69 ± 0.91, *P* = 0.008), red blood cell count (4.13 ± 0.9 vs 4.3 ± 0.9, *P* = 0.001), and platelet count (167.7 ± 91.2 vs 198.5 ± 103, *P* = 0.004). Fasting blood glucose (104.03 ± 43.42 vs 92.1 ± 31.34, *P* = 0.001) and postprandial blood glucose (143.67 ± 72.56 vs 112.1 ± 42.9, *P* = 0.001) were significantly decreased in both diabetic and non-diabetic HCV patients. Patients with lower-limb edema decreased significantly from baseline compared with after treatment [16 (53.30%) vs 7 (23.30%), *P* = 0.004]. Adverse drug reactions were unremarkable except for a few cases of epigastric pain and hypoglycemia that did not affect patient compliance.

**CONCLUSION:** *N. sativa* administration in patients with HCV was tolerable, safe, decreased viral load, and improved oxidative stress, clinical condition and glycemic control in diabetic patients.

INTRODUCTION

Egypt has the highest prevalence of hepatitis C virus (HCV) worldwide (15%) and the highest prevalence of HCV-4 (67%) with a predominance of subtype 4a (55%) [1-4].

The natural history of HCV infection and disease progression are influenced by several factors such as age at infection onset, sex, duration of infection, co-infection with hepatitis B virus (HBV), level of HCV viremia and its genotype [5].

HCV is an important etiological factor for the development of hepatocellular carcinoma (HCC) and 25% of HCV patients develop HCC [6]. It has been shown that there is an alarming increase in the incidence of HCC in HCV patients in Egypt [7].

Presently, the only approved therapy for HCV is pegylated interferon-α (PEG-IFN-α) and ribavirin treatment, and their success is heavily influenced by patient adherence, which correlates directly with tolerance to their side effects [8]. Moreover, financial constraints for the combined therapy in many patients often contribute to therapy non-adherence, potentially lowering its success rates [9].

Oxidative-stress-related molecules may act as mediators modulating cellular events responsible for progression to liver fibrosis [10,11]. It has been shown that increased production of reactive oxygen species, in part catalyzed by iron overload, is involved in HCV-related liver damage through a pathway that involves DNA oxidative injury [12].

Silymarin is one of the alternative therapies that has been previously tested for the management of HCV patients who are not candidates for PEG-IFN; however, it has not shown any appreciable effects on viral load [13].

*Nigella sativa* (N. sativa) is used as a food condiment in the Middle East, and its seeds/oil have been shown to possess anti-inflammatory, antiviral and antineoplastic activity in various *in vitro* and *in vivo* studies [14]. The antioxidant effects of *N. sativa* have been shown in the essential oil obtained from six different extracts of its seeds, as well as from a commercial fixed oil [15]. The crude *N. sativa* oil and its fractions have shown potent *in vitro* radical scavenging activity [16].

The effect of *N. sativa* has been evaluated in animal studies. There are many reports of its biological activities including: immunopotentiaion, antitumor, anti-inflammatory, analgesic, antihypertensive, antioxidative, antimicrobial, antibacterial, antifungal, antiprotease and antinematode effects [17-19].

A striking reduction of murine cytomegalovirus (CMV) virus titer in both spleen and liver was found in mice treated with *N. sativa* seed oil compared with control mice [20]. Moreover, oral feeding with *N. sativa* extract suppressed chemically induced hepatic tumors in rats [21]. *N. sativa* treatment has been shown to ameliorate disturbed hematological parameters in diabetic rabbits through modulation of lipid peroxide red blood cell (RBC) membrane content, leading to an increase in RBC count [22].

To date, no studies have addressed the use of *N. sativa* in HCV patients and its potential benefits; hence, we sought to evaluate the efficacy, safety, and tolerability of *N. sativa* supplementation as an alternative therapy in the management of HCV patients who are non-candidates for IFN-α therapy.

MATERIALS AND METHODS

This was a prospective, single-armed, self-controlled pilot study, conducted at the Tropical Medicine Department, El-Demerdash Hospital, Ain Shams University, Cairo, Egypt.

Patients

All HCV patients presenting to the department were assessed for eligibility. Inclusion criteria included all patients diagnosed with HCV with or without cirrhosis who either had a contraindication to IFN-α therapy [23], or had refused or had a financial constraint to IFN-α therapy. Exclusion criteria included: patients on IFN-α therapy; infection with HBV or hepatitis 1 virus; HCC or other malignancies; major severe illness such as renal failure, congestive heart failure, respiratory failure or autoimmune disease; or non-compliance to treatment. Informed consent was obtained from all patients, and the institutional ethical committee approved the study protocol, which conformed with the ethical guidelines of the 1975 Declaration of Helsinki.

Methods

Hepatitis markers were assessed for all patients at enrollment, including: hepatitis B core immunoglobulin G, hepatitis B surface antigen, and HCV antibody. All eligible patients were subjected to the following at enrollment and after 3 mo therapy: (1) Full clinical assessment with an emphasis on hepatosplenomegaly, jaundice, palmar erythema, flapping tremors, spider naevi, lower-limb edema, and ascites; (2) Abdominal ultrasonography; (3) Laboratory investigations including complete blood count, liver functions [aspartate aminotransferase (AST), alanine aminotransferase (ALT), total proteins, albumin, total and direct bilirubin, prothrombin time and international standard ratio (INR)], renal function (serum creatinine, blood urea nitrogen), serum α-fetoprotein, polymerase chain reaction (PCR) for HCV (lower detection limit, < 50 copies) and total antioxidant capacity (TAC); (4) The antioxidants assessed in the estimation of TAC included enzymes such as superoxide dismutase, catalase, glutathione peroxidase; macromolecules such as albumin, ceruloplasmin, ferritin; small molecules, including ascorbic acid, α-tocopherol, β-carotene, reduced glutathione, uric acid, and bilirubin; (5) The assay principle depended...
on the determination of the antioxidative capacity by the reaction of antioxidants in the sample with a defined amount of exogenously provide H_{2}O. The antioxidants in the sample eliminated a certain amount of the provided H_{2}O. The residual H_{2}O was determined colorimetrically by an enzymatic reaction that involved the conversion of 3,5-dichloro-2-hydroxy benzenesulfonate to a colored product; (6) TAC was analyzed using a TAC kit from Bio-diagnostic and measured spectrophotometrically using KENZA (BioLabo) analyzer; and (7) Real-time PCR was performed on COBAS TaqMan 48 PCR analyzer, using Roche COBAS Ampliprep Taqman Kit.

**Drug administration**

After performing the baseline evaluation, all patients received one capsule of *N. sativa* seed oil (450 mg) available as soft gelatin capsules (Baraka; Pharco Pharmaceuticals) three times daily after meals continuously for 3 mo. Patients were followed up every 2 wk throughout the study period for assessing treatment adherence, tolerability and incidence of adverse reactions.

**Statistical analysis**

Statistical analysis was performed using SPSS version 17 software. Numerical data were summarized using means and standard deviations or medians and ranges. Categorical data were summarized as percentages. Differences between numerical variables over two time measurements were tested using paired *t*-test or medians test for non-normally distributed data. Repeated measures analysis of variance was used to test differences between three-time numerically normally distributed variables and Friedman test was used for non-normally distributed variables. McNemar’s test was used to compare categorical data overtime. All *P* values were two-sided, and *P* < 0.05 was considered significant. All authors had access to the study data and reviewed and approved the final manuscript.

**RESULTS**

Thirty patients (16 male, 14 female) with a mean age of 47 ± 10.2 years fulfilled the inclusion criteria and were enrolled in the study. Four of those patients (13.33%) had diabetes and 26 (86.67%) did not. Fifteen patients (50%) had chronic liver disease, five (16.7%) had compensated cirrhosis, and 10 (33.3%) had decompensated cirrhosis.

Patients’ clinical assessment data before and after treatment are presented in Table 1. After treatment, there was a significant decrease in the percentage of patients with lower-limb edema, while there was no change in the percentage of patients with jaundice, palmar erythema, spider naevi or ascites. Laboratory parameters before and after treatment are presented in Table 2.

**Liver functions tests**

After 3 mo of *N. sativa* treatment, the mean HCV RNA levels (PCR) (147028.2 ± 475225.6) significantly decreased relative to their baseline levels (380808.7 ± 610937, *P* = 0.001) (Figure 1A). Table 3 presents the PCR responses after 3 mo treatment in patients with chronic liver disease and compensated and decompensated cirrhosis. Figure 2 presents individual patients’ HCV RNA (PCR) values before and after treatment. Table 4 presents the Child-Pugh score and PCR response at baseline and after 3 mo in patients with compensated and decompensated cirrhosis. All cirrhotic patients (compensated and decompensated) showed no change or an improvement in their Child-Pugh score, patients presented with variable Child-Pugh score, yet the proportions’ numbers were small for a valid statistical test. There was a significant increase in total

Paired *t*-test for all parameters, median test (equivalent to Wilcoxon matched pairs test) for polymerase chain reaction (PCR) levels. RBCs: Red blood cells; WBCs: White blood cells; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; INR: International normalized ratio; BUN: Blood urea nitrogen; AFP: α-fetoprotein; TAC: Total antioxidant capacity.
protein and albumin levels after treatment. However, there was no significant change in liver enzymes (AST and ALT), bilirubin, or INR. Renal function did not show a significant change from baseline. TAC showed a significant increase after treatment (1.612 ± 0.56) relative to the baseline values (1.35 ± 0.05, \( P = 0.001 \), Figure 1B). Hematological functions varied significantly after 3 mo of \( N. \) sativa treatment. There was a significant increase in RBCs (\( P = 0.001 \)) and platelets (\( P = 0.004 \)) and a significant decrease (\( P = 0.013 \)) in white blood cells.

### Blood glucose

There was a significant decrease in both fasting and post-prandial blood glucose after treatment (\( P = 0.001 \)).

### Incidence of side effects and drug interactions

The reported side effects throughout the study period were gastritis in one patient (3.33%) and hypoglycemia in five (16.76%); of whom two had insulin-dependent diabetes, and the other three had advanced liver cirrhosis with possible glycogen depletion. Both side effects were treated and did not hinder completion of therapy. The only reported drug interaction was hypoglycemia due to concurrent use of insulin and \( N. \) sativa, which aggravated its hypoglycemic effects.

### DISCUSSION

The main findings of our study were that administration of \( N. \) sativa significantly decreased HCV viral load, increased total antioxidant activity and total protein and albumin levels, lowered blood glucose levels, and improved lower-limb edema.

The anti-inflammatory, antiviral and antineoplastic activities of \( N. \) sativa have been previously documented in various \textit{in vitro} and \textit{in vivo} studies\(^{10,11}\). In the current study, \( N. \) sativa administration resulted in a significant decrease in viral load, with 16.67% of patients becoming seronegative, and 50% showing a significant decrease in the quantitative viral count. Among these, 66.7% had cirrhosis and 33.3% had chronic liver disease, implying antiviral activity. Patients with compensated and decompensated cirrhosis, either improved or maintained their baseline clinical condition and viral load, and none of them deteriorated, which signifies the potential beneficial effects of \( N. \) sativa administration, as reflected by improvement in HCV RNA responses and clinical condition reflected in Child-Pugh class. Although the subcategory of cirrhosis patients was not large enough to detect significance, we recommend that larger studies should be conducted in patients with cirrhosis to confirm the potential beneficial effects offered by \( N. \) sativa, which might improve patients’ overall outcome. To the best of our knowledge, this is the first human study to evaluate the effects of \( N. \) sativa on viral load in patients with HCV infection. Our findings of improved viral load could be explained by the results of a previous study of murine CMV\(^{24} \), which showed a significant increase in macrophages and CD4\(^{+} \) T cells, with a significant decrease in viral titer and increased serum IFN-\( \gamma \) levels in animals treated with \( N. \) sativa\(^{24} \).

Oxidative-stress-related molecules have been shown to modulate cellular events responsible for the progression of liver fibrosis\(^{10,11} \). Moreover, HCV-related fibrosis, cirrhosis and liver failure have been found to be the result of an adaptive immune response to HCV-infected cells\(^{25} \), which is mediated by induction of endoplasmic reticulum and oxidative stress and downregulation of antiapoptotic proteins nuclear factor-\( \kappa \)B and Bcl-xl in infected hepatocytes\(^{26} \).

In our study, \( N. \) sativa administration significantly increased TAC in HCV patients, implying the potential protective effect of \( N. \) sativa by halting the oxidative stress that contributes to disease progression. Further-

HCV: Hepatitis C virus; PCR: Polymerase chain reaction.
more, it is tempting to propose that increasing antioxidant capacity, with its cytoprotective role, contributed to decreasing the viral load.

The antioxidant effects of *N. sativa* have been previously elaborated in animal models of liver ischemia, in which it improved the antioxidant capacity and reduced oxidative stress\(^{[27]}\). Moreover, *N. sativa* increased hepatic glutathione and reduced elevated hepatic serum enzymes in carbon-tetrachloride-treated mice, ameliorating its hepatotoxic potential\(^{[15,28]}\).

Some patients with acute and chronic liver disease develop diabetes mellitus\(^{[29,30]}\). HCV infection may also contribute to the development of diabetes, which has been observed in 21% of HCV-infected patients\(^{[31]}\), and glucose intolerance has been seen in patients with HCV infection, compared with controls with liver diseases\(^{[32-35]}\).

Insulin resistance is one of the pathological features in patients with HCV infection that may be associated with life-threatening complications, making HCV-associated insulin resistance a therapeutic target at any stage of HCV infection\(^{[36]}\).

Our study showed that *N. sativa* treatment significantly decreased blood glucose levels in HCV patients, implying that it might offer a potential modulatory effect on HCV-induced glucose intolerance. This effect was beneficial in the control of diabetes in HCV patients because it allowed us to lower the insulin requirement. Similar results have been previously shown in a study of patients with diabetes, in whom administration of *N. sativa* (2 g/d) caused significant reductions in fasting blood glucose and 2-h postprandial blood glucose and hemoglobin A1c, and improved insulin resistance\(^{[37]}\).

HCV infection itself can induce autoimmune hemolytic anemia, leukopenia, and thrombocytopenia, even in the absence of IFN-α treatment\(^{[38-42]}\). Hematopoietic growth factors modulating these complications have shown a beneficial role in HCV patients\(^{[43]}\).

*N. sativa* therapy in our study significantly improved RBC and platelet counts in HCV patients, indicating a potential amelioration/prevention of HCV-induced...
hematological disorders. Hence, *N. sativa* may positively affect clinical outcome in HCV patients.

The ability of *N. sativa* to improve hematological indices has also been reported in animal studies in which it increased both the packed cell volume and hemoglobin in treated rats, as well as increased RBC count in diabetic rabbits. The increased RBC count was attributed to lowering of the membrane lipid peroxide level, leading to decreased susceptibility to hemolysis.

Serum albumin is the most abundant plasma protein and is essential for maintaining oncotic pressure of the vascular system. Chronic HCV patients may suffer a decrease in serum albumin level, and improvement in hypoalbuminemia has been shown to improve prognosis and quality of life. Concentrations of < 30 g/L were associated with an 85% chance of liver-related complications at 5 years and a 3-year mortality of 70%, and was predictive of morbidity and mortality in patients with liver cirrhosis.

In the current study, *N. sativa* administration significantly increased serum albumin levels and significantly reduced lower-limb edema, indicating an improvement in clinical condition. Prior animal studies have shown similar effects in rats and broiler chickens in a dose-dependent manner.

*N. sativa* is used in Arab folk medicine as a diuretic plant, the mechanism that can also contribute to its efficacy in decreasing lower limb edema, and its resolution in many patients.

In our study, the number of patients with ascites decreased after treatment with *N. sativa*, although the change was not significant; nevertheless, the change in ascites severity could not be totally denied, because the degree of ascites was not assessed sonographically. We hence recommend assessment of ascites incidence and severity in future studies to confirm these results.

The safety and tolerability of *N. sativa* have been previously documented in various clinical trials. However, to date, clinical studies addressing *N. sativa* efficacy, safety and tolerability in HCV patients are lacking. Our study has shown that *N. sativa* was tolerable in all patients, and the only side effects reported were one patient with epigastric pain that was controlled with antacids, and five patients with hypoglycemia, two of whom had diabetes and were receiving concomitant insulin and the hypoglycemia did not recur after decreasing the insulin dose. Of note, the dose of *N. sativa* used in the current study was (1.35 g/d), which was slightly lower than in the other studies - 2 g/d used by Bamosa et al. - because this dose was available in the Egyptian market and was close to the doses previously used. Although *N. sativa* in such patients had significantly positive effects on many parameters, perhaps higher doses or longer durations of therapy may accentuate such appreciable effects. Further studies are needed to confirm such findings.

It can therefore be concluded that *N. sativa* administration can have a potential beneficial effect on HCV disease progression and outcome through its prominent antiviral, antioxidant and immunomodulatory effects and can minimize HCV-related hematological complications.

Our study had some limitations. This was the first clinical study to be performed in HCV patients and larger studies are required to confirm the results of the current study. We did not assess all patients for the amount of ascites after therapy sonographically, because such a favorable effect of *N. sativa* was not anticipated. Hence, in view of significant improvement of serum albumin, this effect of *N. sativa* on the amount of ascites needs further study. Liver biopsy was not performed, because the patients were either not eligible or refused the procedure.

In conclusion, *N. sativa* administration in HCV patients is safe and tolerable and results in a significant improvement in viral load, oxidative stress and laboratory markers. Moreover, the clinical improvement and better glycemic control in patients with diabetes indicate a potential role for *N. sativa* in improving the clinical outcome of HCV patients. We recommend larger controlled multicenter randomized studies for longer periods for evaluation of the potential beneficial role of *N. sativa* in HCV patients with and without concurrent IFN therapy.

**ACKNOWLEDGMENTS**

We wish to express our gratitude and appreciation to Dr. Inas A Elattar, Professor and Head of Department of Cancer Epidemiology and Biostatistics, at the National Cancer Institute, Cairo, Egypt for her statistical evaluation and review of this study.

**COMMENTS**

**Background**

Hepatitis C virus (HCV) is an important etiological factor for the development of hepatocellular carcinoma. Pegylated interferon-α (PEG-IFN-α) and ribavirin treatment are the only currently approved therapy for HCV with variable response rate, and a success that is heavily influenced by patients’ response rate, adherence to treatment, and tolerance to side effects. Moreover, the financial constraints for the combined therapy in many patients often contribute to their non-adherence to therapy, potentially lowering its success rates. *Nigella sativa* (*N. sativa*), a food condiment used in the Middle East, has shown anti-inflammatory, antiviral, antioxidant and anticancer activities in various in vitro and in vivo studies. To date, no studies have addressed the use of *N. sativa* in HCV patients and its potential benefits.

**Research frontiers**

*N. sativa* is a natural food supplement, and has shown beneficial antioxidant, antiviral, anticancer and immunomodulating properties in various in vitro and in vivo studies, but HCV studies are lacking. In exploring the potential role of *N. sativa* in improving HCV patients’ clinical outcome, the research hot spot is its beneficial effects on reducing viral load, improving antioxidant capacity, alleviating hematological parameters, and improving blood glucose control, especially in diabetes. All of which could have a potential beneficial effect on HCV patients’ responses and amelioration of HCV-related complications.

**Innovations and breakthroughs**

No prior clinical trials in HCV patients have evaluated the use of *N. sativa* and its potential beneficial effects. No studies have addressed any alternative treatments for IFN non-eligible patients or those who refuse or cannot tolerate IFN therapy. *N. sativa* offers hope for a safe tolerable alternative to those patients who cannot tolerate IFN or have a contraindication to its use. Moreover, *N. sativa* has a potential benefit in improving clinical outcome. It showed a preliminary improvement in viral load and antioxidant levels that could provide a potential cure for HCV infection. *N. sativa* also improved the hematological profile and to-
tual protein and albumin levels, which contribute to HCV-induced complications. Moreover, N. sativa decreased blood glucose levels, and hence decreased insulin requirement in patients with diabetes.

Applications
The study results suggest that N. sativa is a potentially beneficial, safe and tolerable alternative in IFN non-eligible HCV patients. It can improve clinical outcome, ameliorate HCV-induced hematological and diabetic complications, and improve lower-limb edema.

Terminology
Viral load, also known as viral burden or viral titer, is a measure of the severity of a viral infection, and can be calculated by estimating the amount of virus in an involved body fluid, for example, RNA copies/mL blood plasma. Human serum albumin is the most abundant protein in human blood plasma. It is produced in the liver and constitutes about half of the blood serum protein. It transports hormones, fatty acids, and other compounds, buffers pH, and maintains osmotic pressure, among other functions. Total antioxidant capacity measures collectively the amount of antioxidant components of the body that reflects the body’s capacity to combat oxidative stress.

Peer review
This was an interesting study in which the authors treated HCV patients with N. sativa, a food condiment used in the Middle East.
